PREPARATION OF THIS DOCUMENT

The parallel progress made in recent years both in our understanding of seaweeds, and in the growth of the seaweed industry, were addressed by Dr. J. MacLachlan, then Chairman of the International Seaweed Association, in his opening address to the Eleventh International Seaweed Symposium held in Qingdao, People's Republic of China, June 19-25, 1983. At this same symposium, discussions between FAO, the Academia Sinica and the International Seaweed Association, focussed on the requirement for training in applied seaweed activities. The need for a handbook or guide to practical phycology was also taken into account for the management both of wild seaweed resources and seaweed cultivation by man. From these discussions, it became clear that it is premature to look for such a handbook in the near future, given that although great strides have been made in understanding the biology and natural chemistry of seaweeds, relatively little has been written of global relevance on practical aspects of harvest and cultivation. The present set of case studies, by providing a detailed description of a range of such industries, aims at providing some of the basic elements from which such a broader and more relevant summary can be drawn. At the same time, these studies themselves can be of direct value to those working in the present seaweed industries.

Doty, M.S., J.F. Caddy and B. Santelices 1986 (eds.). Case studies of seven commercial seaweed resources. FAO Fish.Tech.Pap., (281): 311 p.

ABSTRACTS

Seven case studies are presented on commercial seaweed resources; five on wild crops, respectively Ascophyllum nodosum, Chondrus crispus, Gelidium, Laminaria longicruris and Macrocystis, are provided along with case studies of the farmed crops of Eucheuma and Laminaria japonica. Individually the cases range from descriptions of the wild crops and their management to the managed production of farmed crops including, in several examples, some information on economics and/or processing. These initial seven cases range from those emphaizing but one species from but one part of one country, to studies of a genus as it occurs commercially throughout the world.

Foreword

Seaweeds are of direct importance to man as a dietary supplement/food additive/source of industrial feedstock and as a base for synthesis of a wide range of chemical products. They are of indirectly importance as contributors to natural food chains and habitats supporting commercially important marine fish and shellfish. Except for a few areas of the world however; such as in the Asian region/their potential for contributing to coastal economies of developing countries has been largely unrealized to date and there is a general lack of information on how this resource may be used productively. As noted recently by Caddy and Fischer (1984): "Seaweeds pose the same questions to the resource manager with respect to national harvesting strategy as do commercially important marine animals on the one hand, and the optimal management of forest and pasture stands in the terrestrial context, on the other. The same important questions should be asked in relation to harvesting strategy, namely:

"(1) Where are the resources, of what kind, and how much? What are the possible alternative uses and markets for these kinds of resources?

> "(2) What is the rate and time of harvesting needed in order to maintain a sustainable optimal harvest of the wild resources?
>
> "(3) What are the appropriate levels of investment in manpower and equipment needed to achieve the above optimal harvesting rate in both wild and cultivated systems without wasting scarce economic resources?
>
> "(4) What, if any, are the indirect impacts of harvesting wild crops or farming on other resources in the ecosystem?"

Although an attempt at addressing the first of these considerations was made by Michanek (1975), and the second by Naylor (1976) and McHugh & Lanier (1983), we are clearly still at an early stage in beginning to realize the economic potential of this important grouping of organisms. The large scale culture of unicellular algae, and the culture and wild harvest of seaweeds or macrophytes are potentially an important addition to those other major spheres of human activity, namely agriculture, forestry and fisheries, which now provide most of our naturally renewable organic materials.

The utilization of marine algae is still in its infancy, and despite numerous articles scattered through the scientific literature there are few general accounts that provide the manager of coastal seaweed resources with practical information. There is a general lack of guidance on the management of wild seaweed resources; some of which are unexploited, some overexploited. Many are of ecological importance to fisheries and several form the basis for the rapidly growing field of seaweed farming.

Paradoxically, in comparison with mariculture of marine fish and shellfish, the technical problems of growing marine algae commercially are relatively simple, and are fairly well understood, as can be seen by the case studies included here. In contrast, the problems of market development for algal seaweed are generally more difficult than for the animal seafoods. This is because more sophisticated treatments are required for using the algae either directly as food, or extracting them to make a wide range of valuable chemicals available.

The chemical applications of seaweeds in particular support sophisticated, capital-intensive industries in developed countries as extraction and purification of a wide variety of products is now undertaken. Here, economic constraints both with respect to capital, equipment and labour intensive cultivation methods, and generally low unit prices paid for the product, are the main constraints, but are only touched on briefly here. A companion volume to the present series of case studies is now being planned, which will deal in more detail with special topics relevant to seaweed harvest and culture, such as approaches to management and assessment of seaweed resources, processing, legal aspects and economics.

Introduction

This report applies the case study approach to seven of the more important and diverse world seaweed resources, to bring out some of the main factors affecting their rational production. Less emphasis is placed here on the ultimate uses of seaweeds, which range from their utilization in human food and animal foodstuffs, to their roles as food additives, in water purification systems, pharmaceuticals and as a source of biomass for power production among many other uses.

The editors are conscious of the fact that the seven case studies made available to us within the constraints of the present co-operative study do not cover all of the main types of seaweed resources of importance to man: for example, the production of seaweeds for direct human consumption especially in Japan and China is best represented here by the study on the Chinese Laminaria industry, but some of the economically most important resources are destined for other uses than directly as food. The problems faced on the production side are broadly similar in most cases however, and are likely to be addressed with some modification in one or other of the seven studies presented here.

As human populations increase and strive for better things in life, markets are created for more and more food and the luxury accoutrements of modern society. Among them are many products that require such hydrocolloidal materials as seaweeds produce. These materials are largely suspensoids which tend to keep finely divided particles or droplets separated and in suspension in liquids as in foods that are prepared by suspension in milk or water. As gels they may do the opposite; i.e., keep water suspended in solids, as in the preparation of ice-cream where the result is microcrystals in place of the sandy mouth feel of some ice-creams lacking them. They prevent the scorched taste characteristic of older forms of condensed or evaporated milk. They make many confections, foods and other modern substances possible such as cake icings that don't melt or become sticky at ambient temperatures.

The release of medicines by pills that burst only at the appropriate place as they pass through the intestinal tract are often the result of appropriate coatings of algal materials. Of algal origin are some of the world's most effective antihelminthics. Algal hydrocolloids provide the substratum for many horticultural abd biotechnological procedures such as coating seeds with pesticides and fertilizers and such as used in tissue culture, cytoplast fusion and other genetic mechanics. They produce substances that seem to be effective against some of today's most aggravating viral infections and much more.

Traditionally the seaweed of commerce has been produced from harvesting wild crops. As demands for seaweed have grown, their production by farming has proven attractive for its reliability in respect to quality and volume as well as lower costs. Thus we see the wild crops of Chondrus crispus and Laminaria longicruris, which have contributed so much to the history of seaweed use in the Western Hemisphere, being replaced by the farmed crops from other species in the Orient and Old World Tropics and by other wild crop species from the lower labour cost areas of the Southern Hemisphere. In the case of Eucheuma. shifting from wild cropping to farming has largely involved the same people in the same geographic areas and economic levels; so the change has been welcomed.

The reader will note that there is a wide range of sophistication in respect to the production of the different genera. Gelidium (and most all other agar sources but Gracilaria) is strictly still from wild crops with recognition of clear chemical differences in the agar from the different species involved, though there is little published knowledge of these differences. Our understanding and management of Ascophyllum and, even more so, Macrocystis. wild crops almost approach farming but without great concern in the literature for quality or yield of the hydrocollooid product. Yet the quality of the alginate from different genera and seasons is of primary concern to manufacturers.

Each of the seven seaweed chapters began with the same outline, but as the nature of the production of each is so very different, each chapter has come to have some unique features. However, the basic approach has been to provide the reader with the classical knowledge from science first, then the more experimentally developed specifics leading to crop management and, finally, utilization. The sequence is roughly that of the following ten numbered sections:

1 - Identity of the crop
2 - Distribution, ecology and metabolism
3 - Life history
4 - Population structure and mortality
5 - Productivity of the resource
6 - Method of harvesting and harvesting cycle
7 - Equipment used for harvesting of the resource
8 - Protection and management of the resource
9 - Utilization, processing and economics
10 - References

We hope that the provision of the available information in the above outline will tend to illuminate the gaps in the present information while providing that publicly available for these seven seaweeds. Thus the purposes include encouraging readers to fill the obvious gaps in the technology, to undertake research toward improving present practices and to write new case studies for others of the 25-odd seaweeds of importance in world commerce today.

Ascaphyrion nodosum and its harvesting in Eastern Canada

ABSTRACT

Ascaphyrion nodosum, known from Nordic western mercury, is detached rubber from the Cove Zone to the Algoma North cohort. It reaches Canada for the 1.5 km² kelp-dominated zone of the Algoma North cohort, where it is the most abundant large brown alga in the subtidal zone between 2 and 20 metres depth. Its distribution in Canada is restricted to

Figure 17. The major factors affecting recovery of *Ascophyllum* biomass.

Figure 18. The major components of the harvesting and post-harvesting operations for *Ascophyllum* in Canada.

5.3 Economics of harvesting techniques

Harvesting *Ascophyllum* with an endless cutter-bar rakes yields 2-3 tons per hour (estimated dry-ton (4-5 hours). Capital investment is dependent on the size and type of vessel used for harvest and transport. A 5.5-m outboard powered boat costs some $30,000 (1979 to 1981 dollars). Most operations require a larger boat or barge for several harvesters and such may cost Canadian $32.50 d-1 amortized over 10 years (Craig and Hanic, 1975). To complete drying of the raw material a transport vehicle and a dryer are also required. A truck may cost $25,000 and a dryer $50,000 (1979 to 1981 dollars) depending on the size and type. Operating costs are dependent on the way costs would be at least doubled. One can test for regional differences in costs by comparing the following data. Excluding of drying operations, labor and capital costs were Canadian $10.65 respectively per ton; drying added Canadian $4.79 labor and Canadian $2.47 capital.

Mechanical harvesting increases the productivity per individual but greatly increases the capital investment. Harvesters have handled 2 to 3 t h^{-1} but costs Canadian $75000 per unit. An average yield of 12.5 wet ton per day and 125 operational days per year was used to calculate operational costs (**Table 9 and 9**). If fresh materials are transported to a dryer, the cost is Canadian $0.50 per wet ton (Craig and Hanic, 1975). Total capital investment for a harvester, boat, truck, and dryer would be more Canadian $200,000 capital costs, amortization over 10 years with 20 percent residual value of capital (Table 9) and a labor cost of Canadian $37/h. If drying is included in a multiple of harvesting units (12-15 t d^{-1} raw costs are Canadian $36.71 per ton. The Norwegian harvester capital cost is approximately Canadian $100,000 (Table 10). Operating costs are Canadian $0.50 per wet ton. Total capital investment for a harvester, boat, truck, and dryer would be more than the latter, cost rather circumstances would suggest cutting costs per ton are the same (Table 10). Transport overland would increase in 25 t capacity truck and crane at a cost similar to that in Canada.

Persons hand harvesting *Ascophyllum* use this activity as a 6% to 20% supplement to their annual income. Alternative income sources during the summer months are ground fish, fishing, or aquaculturing; hence fishing is the major source of income during the winter months (Craig and Hanic, 1975; Hanic and Rodrick 1982) Some inequities between *Ascophyllum* and *Chondrus crispus*, harvesting from on either alternating tides or using the low tide period for *Chondrus* and rising or falling tides for *Ascophyllum*. The latter is a subtidal species and the former is intertidal (Craig and Hanic, 1975; Hanic and Rodrick 1982). Craig and Hanic (1975) found it necessary for a company to operate at a loss for *Ascophyllum* as a cutter from Nova Scotia Seaweed Industries Limited operated in the early fall and spring. Alternate employment is labeled fishing or utilization of the Canadian Unemployment benefit program. Harvesting income comprises 65 to 100% of employment income for these harvesters. Harvesting is a part-time activity for most harvesters (Craig and Hanic, 1975; Hanic and Rodrick 1982). Harvesters fish for 65 to 70 days, *Ascophyllum* harvesting individually hiring and marine plant harvesting operations (Craig and Hanic, 1975; Hanic and Rodrick 1982).

Table 9. Capital and operating costs associated with hand harvesting of rockweed in Year 1, assuming that all equipment except holding nets and the collecting crew are shared with other businesses and that these nets would be used for 5 days per week for 30 days per year (proportionately extended amortization rates if used less). A mean daily harvest of 5.4 wet metric tons per day was assumed for a three-person crew. (Sharp and Nash 1975).

6. AQUACULTURE

Until recently the aquaculture of macrophytes, such as *Ascophyllum*, was of minor importance because of many North Atlantic shores was not considered economically viable. The desire to control composition of phycoloid and products has justified applied research on culture techniques.

A spore technique first developed by N. Hanic (University of Prince Edward Island) and subsequently modified has been developed to grow *Ascophyllum* on planting anchors (Strauss and Ruther, 1983). Spraying with unsterilized seawater and pulse feeding of nutrients obtained 14.3 g m^{-2} d^{-1} Similar experiments with a multiple tier system (Strauss and Ruther, 1983) yielded 10.4 g m^{-2} d^{-1} (Strauss and Ruther, 1983). Yield of 1.5 kg m^{-2} was obtained in 6 months (Strauss and Ruther, 1983). Cost of *Ascophyllum* at a cost of U.S. $150 for 100 kg (Strauss and Ruther, 1983). Cost of harvesting and delivering the factory naturally grown *Ascophyllum* is approximately US $140 per dry ton (Bow Scientific 3).

7. PROTECTION AND MANAGEMENT OF THE RESOURCE

7.1 Regulations
7.2 Management

7.1 Regulations

Local shorelines recognized the problem of over harvesting *Ascophyllum* resources, as observed in Europeanes possible in the Maritime Province (C. MacFarlane, pers. comm.). Provincial governments enacted Sea Plants Harvesting Acts in response to the advice of seaweed experts. These regulations included harvesting open seasons and limits on the number of employing interests only to prevent holdfast loss by dragging cutters height of 6.7 cm above the substrate to allow regrowth.

The Sea Plants Act of Nova Scotia made provision for exclusive licenses for designated portions of the shoreline for up to 15 years. Licenses were granted to companies which had been harvesting seaweeds for at least 3 years. The Act also provided for the establishment of a Seaweed Advisory Board to advise the Minister on matters of conservation harvesting and licenses to be issued. In 1979 the responsibility for administering the Act was transferred from the Federal to the Provincial government of Canada. The Sea Plants Harvesting Act was incorporated under the Atlantic Coast Marine Plants Regulations within the Fisheries Act. In 1980 the Atlantic Coast Marine Plants Regulations were amended (SOR/80-1, 1980). Section 3 of the Regulations Part I (Appendix I) The regulations were not altered and the provision was made for alteration of the harvesting season and setting of quotas. Part I (Appendix I).

There were two major changes in regulations from the Provincial Act. Marine Plant harvesting districts No.'s 1-14 were established (Fig. 6) and licenses were personal licenses. The Act was administered by the Minister of Fisheries and Oceans. The Minister was advised by the Provincial Seaweed Board. The Board was to advise on: (a) Enforcement of regulations re the requirements of the Canadian Environmental Assessment and Oceans. Operations Search regional fisheries officers. All purchases of marine plants must be recorded on individual purchase slips for statistical reporting. Due to the large number of small (<1.5 transactions purchasing companies are permitted to report total monthly landings by port to the Statistical Branch of Fisheries and Oceans Canada. In areas where less than 3 companies are active landings are not made public.

As marine plants form a part of the fish habitat Section 31 of the Fisheries Acts of 1977 provides protection against disruption of the habitat. "No person shall carry on any work or undertaking that results in the harmful alteration, disruption or destruction of fish habitat."

7.2 Management

There are no additional restrictions/quota/season or area of operations which require annual assessment of standing crop. The Research Branch of the Federal department of Fisheries has the mandate to obtain that biological information relevant to resource management.

Biologists are provided with species and regional responsibilities within the research branch. Each regional management advisor must pass this a peer review process known as the Canadian Atlantic Fisheries Scientific Advisory Committee (CAFSAC) and thence as advice to upper level fisheries managers.

To communicate information to the industry/regional fisheries officers and management committees are established. Each has a management, processor/buyers and harvesters. The biologist can present his advice to these committees and the committees can provide recommendations directly to the Minister of Fisheries via an area Director.

8. UTILIZATION

8.1 Chemical and nutritional content
8.2 Human foods
8.3 Animal feeds
8.4 Fertilizer
8.5 Industrial products and processes

8.1 Chemical and nutritional content

The early industrial utilization of *Ascophyllum nodosum* required for practical purposes an analysis of its constituents. Baxter(n.d.)1970 recorded studies of a wide range of organic and inorganic substances in *A. nodosum*. Seasonal/geographical, and inter-thallus variations of water content, trace elements, alginates, and pigments were among the topics reviewed (**Table 10**). Much more detailed data on some of these constituents were recorded and additional substances identified.

Pharmacological research continues to find potential in seaweeds. Fucoidan, as prepared from *Ascophyllum nodosum*, shows excellent metal binding abilities and binds 1.5 times more than the lowest metal binding seaweed *Pelvetia fastigiata* at pH 4. 1979). In vivo experiments a 67% reduction in lead absorbed by rats from their gastrointestinal system was observed.

The anthropo/nutraceutical activity of sterols in algae has led to studies of their content in *Ascophyllum nodosum* (Knights, 1970; Sahi et al. 1974). Fucosterol comprises over 90% of the sterol content of *A. nodosum*. The presence of other sterols was considered the result of oxidation (Knights, 1970). A more detailed study of sterol content found 0.10% sterols of dry weight, of which fucosterol was 95% with positive identification of five other sterols of which saringosterol was 6% (Sahi et al. 1974). Fucosterol is reported to be a component of cholesterol. *Ascophyllum* based on human feed groups. No differences were found in hemoglobulinic activity between Alaska regions (Buchanan et al. 1975).

Table 10. Average composition of Norwegian seaweed meal (Baardseth, 1970 from Jensen Nobb and Seeber 1966).

Component Content in %	Component	Content in %	Trace Elements	Mg/kg
Moisture	12-15	%	Crude fibre	9%
Ash	17-22	%	Crude protein	20 %
Alginic acid	25-28	%	Ether extract	2-4 %
Mannitol	10-15	%	Nitrogen free extract	40-50%
Laminarin	3-5	%	Iodine	0.1-0.3 %
N	2-3.3	%	Calcium	0.5%
P	0.1-0.3	%	Ascorbic acid	100-2000 mg/kg
Cl-	3-1.4	%	Carotene	30-60 mg/kg
Na	2-3.5	%	Thiamine	3-5 mg/kg
K	3-5	%	Folic acid	0.1-0.3 mg/kg
Ca	1-1.5	%	Folic acid	0.1-0.5 mg/kg
Mg	0.1-0.15	%	Biotin	1 mg/kg
S	30-100	mg/kg Riboflavin		5-10 mg/kg
Fe	100-500	mg/kg Pantothenic acid		10-20 mg/kg
Mn	150-1000	mg/kg Vit.b$_{12}$		0.01-0.05 mg/kg
Mn	10-50	mg/kg Vit.K		10 mg/kg
Cu	150-1000	mg/kg N		2-3 % mg/kg
Co	30-200	mg/kg Ni		2-5 mg/kg
Zn	100-500	mg/kg Pb		10-20 mg/kg

* SFU = Sundstrand feed units
Algae and 100-1000 mg/kg N-free extractives 500-2000 mg/kg

Vitamin content of *Ascophyllum nodosum* was extensively catalogued by Baardseth (1970). However, several concurrent papers were not included in the synopses. Vitamin B$_{12}$ content of 0.01-0.05 mg kg^{-1} was recorded by Buchanan et al. (1975) and Jensen Nobb and Seeber (1966). Vitamin K content was recorded at 10 mg kg^{-1} (Jensen Nobb and Seeber (1966). Total tocopherol was reported in September at 1000 mg kg^{-1} (Buchanan et al. 1975). Vitamin C was detected in fresh samples with immersion and immersion periods. Optimally growing plant sections contained less total tocopherol than older portions of the plant (Sahi and Chari, 1979). Vitamin C in the form of B ascorbic acid was found in concentrations of 0.1-0.5 mg kg^{-1} (Jensen Nobb and Seeber, 1966). Vitamin A activity was found in the form of carotene and 0.1 mg/kg in another source. Higher carotene content in August (Craigie Algorithm Ltd. et al. 1975). Thiamine, riboflavin, folic acid, and Aagnall (Gabrielsen et al. 1975).

Anti-microbial compounds were detected in *Ascophyllum nodosum* as early as 1954 (Vacca and Wiskin1954). Recent studies have found some summer antimicrobial activity but none in spring or winter (Ananova and Nikitin 1979). Activity was found to be greater against gram positive than gram negative bacteria.

Descriptions of alginate structure and its composition in a variety of algal species has been ongoing since 1970. The sequences of uronic acid, building blocks of alginate, have been described by Haug and Larsen (1962) and Haug et al. (1967). Alginate is composed of D-mannuronic acid and L-guluronic acid. Mannuronic acid and guluronic acid residues are linked together in 1-4 linkages to form linear polymers. Alginate is composed of blocks of mannuronic acid, guluronic acid, and alternate sections in older portions of the plants (age, ed.). Other polysaccharides were isolated from *A. nodosum* and their structure examined. Fucoidan was isolated and described as a sulphated polysaccharide, existing as a building block of the sequences fucose-2-sulphate (Haug et al. 1967).

Concern for the effects of hydrocarbon spills in our coastal environment led to an assessment of natural hydrocarbon background levels in various benthic algae (Blumer et al. 1970). Algae were predominate in *Ascophyllum nodosum* and other tested brown algae. Polynuclear hydrocarbons occur only in the reproductive tissues of *A. nodosum*.

8.2 Human food

Ascophyllum nodosum is not normally used directly as a foodstuff but may appear as a constituent of health food tablets. The polysaccharide algin extracted from *Ascophyllum* is used in a wide variety of foods. Algin is used as a thickening agent in ice cream, salad dressings, sauces, puddings, pharmaceuticals, cosmetics, polishes, preparations and agents and alternating segments of these acids. Acceptable daily intake of algin is composed of 66% mannuronic acid, 33% guluronic acid the ratio of these components can range between 1.40 and 1.56 (Clifford and Kovacs, 1980). Common food uses for alginates include prepared pie fillings, instant mixes and beverages.

8.3 Animal fodder

Ascophyllum nodosum is used as a stock feed additive. It may make up to 5% of the diet for poultry, sheep, cattle, pigs and horses. The trace element and vitamin components of *Ascophyllum* meal are the active ingredients for growth of cattle, milk production, color in eggs and improving wool color in sheep (Neish and Jensen 1982). Canada has imported seaweed meal for an use as a fodder supplement, significant quantities of seaweed meal have been formally animal feeds are imported from Iceland.

8.4 Fertilizer

The use of fishing *Ascophyllum* as a soil conditioner, source of trace elements and general growth stimulant began in the sandiest settlements of Maritime Canada. European settlers brought this custom from centuries of use in Europe. Liquid seaweed extracts developed since 1950 and available powders are used as in foliar sprays. Extracts from *Ascophyllum* are used in the production of fertilizers in Canada, Norway, Iceland, Ireland, Scotland, France, Germany, Spain, Portugal, Japan, and the United States. Kelps and gelidiaceae are also reported for seaweed fertilizers. Seaweed meal, powder, and liquid extracts. Soluble powders are the most sprays increased protein content of soybeans, soluble solids in tomatoes and yield of Southern pea (Arnon, 1975).

A liquid extract of Nova Scotian *Ascophyllum nodosum* was produced in Yarmouth by Agway Seaweeds Ltd., but commercial production did not follow.

8.5 Industrial products and processes

Sodium alginate is used as a part of a sizing solution for linen board. Alginate enhances penetration of adhesives, acts as a carrier in fire reactive dyes. Its gelling properties are used in the production of printing pastes for textiles and in the production of rubber latex foam. Alginate is used in the production of dental impressing cloths and creamers. The industrial preparation of *Ascophyllum nodosum* extract is described in a section in flow sheet on **(Fig. 19)** to present production of the liquid extract.

Figure 19. Flow chart describing major steps in the manufacture of alginic acid (Clifford and Kovacs, 1980).

APPENDIX I EXCERPTS FROM: MARINE PLANTS/ATLANTIC FISHERY REGULATIONS

PART I GENERAL

Interpretation of Crown Trees and Quotas

4. A Regional Director-General may, by order, vary any close time or fishing quota fixed by these Regulations.

5. Subject to Section 4, a Regional Director-General varies a close time or a fishing quota, he shall, by one or more of the following methods, give notice of the variation or the period for which it is to be affected by the variation:

SCHEDULE XXVI
(s. 34 and 36)

MARINE PLANT HARVESTING DISTRICTS AND CLOSE TIMES*

Item	Column I: Harvesting Districts	Column II: Period
1	District 1: Waters adjacent to the west shore of Prince Edward Island between Point Prim, Prince County and North Cape, Prince County	November 1 to June 15

Chondrus crispus Stackhouse*

ABSTRACT

The Northwest Atlantic Regional Study is the basis of a successful county fair competition in the north of Wales and St. Lawrence where the species is of principal concern.

5.1 Standing stock and yield

Standing crop estimates (expressed only once) have been identified in MPHS 1. Based on destruction of enormous effort (Pringle and Scheibling, 1994) series of these estimates (Pringle and Scheibling, 1994). The more study ranged in area from 10 m to an Ontario beach to 10 m in Maryland forests, with mean shell densities ranging from 0.2 to 1.5 kg m-2 (Pringle and Scheibling, 1994). The more study ranged in area from 10 m to an Ontario beach to 10 m in Maryland forests, with mean shell densities ranging from 0.2 to 1.5 kg m-2 (Pringle and Scheibling, 1994). The more study ranged in area from 10 m to an Ontario beach to 10 m in Maryland forests, with mean shell densities ranging from 0.2 to 1.5 kg m-2 (Pringle and Scheibling, 1994).

Figure 5a. The disappearance of MPHS 1 in the ice thinning zone marina (and harvesting) experiment. The **Ontario** Ministry of Natural Resources **Southeastern** portion of MPHS 10 in the eastern corner of MPHS 5.

Production estimates have been made for a number of populations. The MPHS, the most annual standing crop biomass of 1.2 and 1.5 kg m-2 (Pringle and Scheibling, 1994). The most annual standing crop biomass of 1.2 and 1.5 kg m-2 (Pringle and Scheibling, 1994). The most annual standing crop biomass of 1.2 and 1.5 kg m-2 (Pringle and Scheibling, 1994).

APPENDIX I: Terms of reference for the southwestern Nova Scotia Marine Plants Advisory Committee Committee

1. Purpose and Objective

The South West Nova Scotia Advisory Committee will serve as a forum for discussion and consultation among those sectors of the industry and provincial governments having an active interest in the fishery and the Federal Department of Fisheries and Oceans. The Committee shall provide advice and recommendations to the Department's Regional Director-General, through the prescribed reporting relationship, on all policies pertaining to conservation, utilization and enhancement of the marine plants resource.

2. Duties and Responsibilities

The Committee will be responsible for reviewing and offering comment, advice or recommendations on the following:

(a) The establishment of policies to enable implementation or better use of management measures, including examination of guidelines relating to such matters as seasons, closed areas, fishing methods and licensing for the local marine plant fishery;

(b) The establishment of regulations to ensure sufficient conservation and best utilization for its harvest, as well as methods to enable adequate enforcement for such regulations; and

(c) Review the necessity for development programs, including examination of environmental, biological, technical and economic considerations

3. Membership

Meeting on behalf of the Regional Director-General, the Department's Area Manager in the Southwestern Nova Scotia area will be the Chairman of that Committee. Representation will be drawn from all sectors dependent upon the marine plank resource. Membership shall normally be limited to a maximum of sixteen. The Committee will draw representation from among the following:

- Commercial fishermen/harvester
- Processors
- Provincial government
- Federal government

4. Technical Expertise

As required, the Committee may draw upon the expertise of the Department's biologists, engineers, economists or other scientific and professional advisors, and may request that these individuals attend meetings for specific purposes.

The production and use of Eucheuma

ABSTRACT

Eucheuma is the commercial name applied to several species of red seaweeds (Rhodophyta) which are harvested from the wild and cultivated in tropical waters. The species are characterized by their lack of calcification, cartilaginous consistency, and the presence of gelatinous carpogonial branches. Eucheuma is a source of phycocolloids (carrageenan) which are used commercially in the food, cosmetic and pharmaceutical industries. Eucheuma is harvested in the Philippines, Indonesia, Malaysia, Tanzania, Kenya, Zanzibar, Pemba, Madagascar, Fiji, Tonga, Cook Islands, Solomon Islands, Vanuatu, Papua New Guinea, Micronesia, Belize, Jamaica, Haiti, Cuba, Venezuela, Brazil and Mexico. Eucheuma is cultivated in the Philippines, Indonesia, Malaysia, Tanzania, Kenya, Zanzibar, Pemba, Madagascar, Fiji, Tonga, Cook Islands, Solomon Islands, Vanuatu, Papua New Guinea, Micronesia, Belize, Jamaica, Haiti, Cuba, Venezuela, Brazil and Mexico.

1. IDENTITY

1.1 Nomenclature

1.1.1 Nomenclature and synonymy

1.1.2 Affinities and homologs

1.1.3 Taxonomic key

1.1 Taxonomy

Eucheuma is a red seaweed with very branches (branches in magnification), and with 90% of the crop is farmed (E. [striatum](#) Schmitz, E. [spinosum](#) (Linnaeus) J. Agardh, E. [denticulatum](#) (N.L. Burman) Collins et Hervey, E. [isiforme](#) (C. Agardh) J. Agardh). Only the latter is cultivated to the EEZ of Fiji. The species are differentiated by the presence or absence of [spines](#) and the [form of carpogonial branches](#).

The taxonomy of the Eucheuma species is controversial, and unclear. The presence of [spines](#) is not difficult due to the wide range of environmentally induced forms in the species. Eucheuma is a source of phycocolloids (carrageenan) which are used commercially in the food, cosmetic and pharmaceutical industries. Eucheuma is harvested in the Philippines, Indonesia, Malaysia, Tanzania, Kenya, Zanzibar, Pemba, Madagascar, Fiji, Tonga, Cook Islands, Solomon Islands, Vanuatu, Papua New Guinea, Micronesia, Belize, Jamaica, Haiti, Cuba, Venezuela, Brazil and Mexico. Eucheuma is cultivated in the Philippines, Indonesia, Malaysia, Tanzania, Kenya, Zanzibar, Pemba, Madagascar, Fiji, Tonga, Cook Islands, Solomon Islands, Vanuatu, Papua New Guinea, Micronesia, Belize, Jamaica, Haiti, Cuba, Venezuela, Brazil and Mexico.

Eucheuma - type of the genus and family Eucheumaceae, order Gigartinales, class Rhodophyceae, division Rhodophyta, kingdom Plantae.

Eucheuma - name

h. Estimated total cost of labor w/o supervisory time.	1552.00
(H. Equipment needed	
1 cross bar	18.00
2 heavy knives (e.g. bolos)	12.00
2 stainless steel knives	7.60
4 rattan baskets	28.00
1 plastic container for water	10.00
1 plastic container for gasoline	10.00
Miscellaneous	14.40
Total	100.00
IV. Total estimated cost of materials and installation of a one acre monoline Eucheuma farm	3070.00a/

a/In 1985 this was equivalent to about U.S.$1330.

When government or tradition intervenes, rather than cost of materials, etc., a stumbling block to farming from the would-be-farmer's point of view could be obtaining the right to farm.

An investor would find the weakest place in Eucheuma farming to be in the availability of competent personnel for selecting a site, installing a farm and managing it. The cost of such a manager could be equivalent to the local costs for a non-college-graduated school teacher. In addition the investor would have to obtain clearance to use the site and obtain the initial planting material. **Table 8** displays the materials and their costs for one acre farms constructed in easternmost Sabah, Malaysia, for the State Fisheries Department. These Sabah costs are surely more nearly maximal than minimal if for no other reason than that they included **(Table 9)** two surrounding sets of nets and devices to control herbivorous fish (largely Siganus) and Chelonia midas, the green turtle.

The amount of time required is increased by the travel time to and from the farm construction site and by the tides. At the Sabah sites to which Tables 8 & 9 refer the time on the job was about four hours per man day. This would be different elsewhere.

7.3 Sources of credit and insurance of the crop

Essentially there are no sources of credit or insurance for seaweed crops. In practice the most to be had is provided by the strong ties among the pre-sale seaweed producers and credit with the local merchants.

8. PROTECTION AND MANAGEMENT OF THE RESOURCE

8.1 Management of seaweed resources
8.2 Regulation of seaweed

8.1 Management of seaweed resources

As in many such agricultural industries, there are three levels of management concern plus the government. These may be separated conveniently into a) pre-first sale level of wild crop harvesters and farmers; b) post-first sale entrepreneurs and exporters, and c) the ultimate processors. Hollenbeck (1983) and Veltin & Hollenbeck (1982) provide much more.

8.1.1 Commercial relationships

Management of wild crop harvesting has always been largely in local, usually informal or traditional, hands. A typical operation is for a post-first sale entrepreneur to make arrangements with a Eucheuma from a shoreside village merchant. This merchant is often the de facto local government insofar as the harvesters are concerned. In Indonesia he is (Lee Hollenbeck, personal communication) often the traditionally recognized village leader who gets the artisanal fishermen to collect seaweed, often a given or traditional amount. The village leader also arranges the seaweed and sells or barters it to the entrepreneur or trader, who will probably be but a representative of a traditional exporter. In a money-economy situation the village leader, the trader and the exporter may be considered second level interests. The third level interests, the processors, establish commercial relationships which are often agreements to buy a certain tonnage within certain time/quality limits "free and on board" a ship bound for the port nearest the processor's plant.

Table 9. Fish and Turtle Exclosure Fences and Trap Costs. The list of materials is for a square one acre farm ca 210 feet on a side in an area where the tides may rise as high as two meters. Values are in 1982 Malaysian dollars.

Item & Description	Number needed	Length needed	Weight needed	Amount in M$
A. For fencing:				
(1) Mangrove posts	148	12 ft. long & 2 " diam.		44.40
(2) Stranded fish net Twine: PE. 380/6 Mesh: 2 1/4" Width: 300 cm Length: 150 ft./roll	3 rolls	880.6 ft.		750.00
(3) Border-line for stranded fish net, 150 ft test			2 kilos	24.00
(4) Wire for securing fish net to posts, 16 inches long	444 pcs.	592 ft.		20.00
(5) For turtle net, 2.5 x 5 meters in standard net units	60 pcs.	946 ft. or 288.5m.	5 kilos	228.00
(6) Mangrove posts for net fencing	60 pcs.	12 ft. by 2" in diam.		20.00
(7) Wire for securing turtle nets to posts, wire pieces 16" long	174 pcs.	232 ft.		8.00
B. Two fish traps:				
(1) Mangrove stakes, 3 meters long by 2 1/2 " in diam.	8 pcs.	10 ft.		2.40
(2) Mangrove stakes, 2.5 meters by 2 1/2" in diam.	8 pcs.	9 ft.		2.40
(3) Many rove stakes, 1 meter by 2 1/2" in diam.	8 pcs.	4 ft.		1.20
(4) Stranded fish net: Twine: PE. 380/6 Mesh: 1 1/4" Depth: 300 cm		32 ft.		7.20
C. Total fencing & trap material costs				1,107.40M

M/In 1985 this was **equivalent to about** U.S.$480.

8.1.2 Government roles

Two governmental groups are often the official bodies of concern: economic development authorities and the fisheries departments (often) of the agriculture department. They usually arise after-the-fact due to their lack of entrepreneurial and physiological capability as well as inceptive, the need to heed the wishes of the politico/economic interests and their traditional thrifts/selfish concerns.

The private sector has been the initiator (Doty 1973b; Adnan & Porse In Mss) and has been initially in control of the first two levels in almost all successful production areas; e.g., to the extent that there is production in Indonesia, Philippines, Taiwan and Tanzania. In Indonesia the Agency for the Assessment and Application of Technology and in Kiribati and Malaysia the fisheries departments have been very positively active in seeking to establish farming.

In the Philippines the national fisheries development science played an unusually successful role by coordinating and contributing its facilities to the expatriate academic and processing interests of industry at the initial development level of both the wild crop harvesting and later the R & D leading to pre-eminence of the Philippines in both cottonii and spinosum farming.

There are no effective formal mechanisms for consultation between the levels of concern in the Eucheuma industry.

There are essentially no regulations effectively governing the harvesting/culture of Eucheuma. What arrangements exist for leasing or private ownership of nearshore or intertidal areas for the purpose have been ineffective or have been applied at the initiative of local fisheries officers and the private sector by what might be called field expediency. In southernmost Philippines, village councils have shouldered the responsibility for individual farmer concessions under the umbrella protection of master concessions from the government obtained by the processors. In some other places government participation in efforts to "farmers" farmer leasing have been as much a barrier to success as an aid.

The concession plans in Indonesia and Malaysia; at least, were established so as to leave passageways for local boat traffic. On reef flats there is no conflict with fisheries useage or with ocean navigation. The farms result in enhanced fish crops, and fish traps and Eucheuma farms do not compete for the same space.

8.2 Regulation of seaweed

To date no specific legislation is known that affects Eucheuma farming. In Hawaii it has been effectively prevented in the past by the classification of all sub-tidal land as conservation, a designation that prevents its economic development. This situation in Hawaii is changing favorably through new legislation. In the Philippines legislative and executive bodies have been ineffective or have been applied at the initiative of local fisheries officers and the private sector by what might be called field expediency. In southernmost Philippines, village councils have shouldered the responsibility for individual farmer concessions under the umbrella protection of master concessions from the government obtained by the processors. In some other places government participation in efforts to "farmers" farmer leasing have been as much a barrier to success as an aid.

The concession plans in Indonesia and Malaysia; at least, were established so as to leave passageways for local boat traffic. On reef flats there is no conflict with fisheries useage or with ocean navigation. The farms result in enhanced fish crops, and fish traps and Eucheuma farms do not compete for the same space.

9. UTILIZATION

9.1 Chemical and nutritional content
9.2 Human food
9.4 Animal Fodder
9.5 Manure
9.6 Industrial products and processes

9.1 Chemical and nutritional content

Industry's only concern for Eucheuma is its carrageenans. Carrageenan is a cell wall component which represents 40 to 75 percent of the seaweed's salt-free dry weight. In addition to carrageenan the cell walls of a Eucheuma contain a small amount of cellulose and minor amounts of other unspecified materials.

Eucheuma reaches the ultimate consumer as whole or particulated, dried material in one of several forms. Commonly the carrageenan may be extracted carrageenan (with or without chemical modification) or in the non-extracted modified form.

Basically carrageenans are d-galactopyranoses alternately paired by alpha 1-3 and beta 1-4 linkages. Their molecular weights may be as high as 400,000. They are typically sulfated though sulfate is lacking (Greer & Yaphe 1984) in beta carrageenan. Seven types are recognized and referred to by the greek letters, beta, gamma, kappa, lambda, iota, mu and nu. Infra-red absorption peaks are present for total sulfate and, respectively, that at any of the 2, 4 or 6 positions. In addition, the different carrageenans are also distinguished by their solubilities in water at different temperatures (Greer & Yaphe 1984) and reactions to different salt solutions as well as the physico-chemical properties of their gels. At present there is considerable question as to their structure, e.g., whether they are purely one or another of the seven types listed above or whether these are blocks of one or another combination with blocks of other types. Relatively low sulfate content and 3-6 anhydro linkages are found to be related to high gel strengths. Milk reactivity and gel strength may be related to potassium and sulfate, respectively, at the 4-carbon positions. Various other radicals may be attached especially at 6-carbon positions.

The nutritional value of Eucheuma and its contained carrageenan are unknown. Its effect on humans is believed to be nil and, in foods containing it, the carrageenans are minor components by weight, though often indispensable for contributing a specific quality to the product.

9.2 Human food

Culinarily speaking, Eucheuma, the fresh or non-dried seaweed itself, adds delightful variety, novelty, and bulk to peoples' diets in various countries where it grows, e.g., as a fresh salad component or as pickles.

The extracted carrageenans provide stabilization and quality to the products in which they are combined. Today, many instant foods that come in powdered form for mixing with cold milk to make them comestible owe their speed and permanence of suspension to the carrageenan modification they contain. A desirable mouth feel is sometimes obtained by adding a carrageenan. Some major toothpastes contain it for its way of holding water in the product and, thus, extending shelf life. The successful suspension of chocolate in milk is perhaps best done with carrageenan. Most if not all evaporated milk nowadays contains carrageenan as the component that makes possible its pleasant flavor and thick, creamy quality.

Aside from "extracted carrageenan", there is the alkali-treated Eucheuma (sometimes spoken of as AMF or AMC, i.e., alkali modified flour or alkali modified carrageenan or semi-refined carrageenan). Making alkali-treated Eucheuma seems to consume most of the nutrient Eucheuma produced, for it is far less expensive than extracted carrageenan. It can usually substitute for extracted carrageenan where a little cloudiness from the small percentage of cellulose present does not interfere.

Both the alkali-modified Eucheuma products and the extracted carrageenans must compete with other hydrocolloids on the basis of amount required to do the job and cost per pound. An outstanding exception is their special effect in some milk products wherein carrageenan is often essential or nearly so. Carrageenans form synergistically desirable substances with other hydrocolloids and are chemically modifiable in many ways, giving them a wide variety of useful special qualities. Guiseley et al. (1980), Whistler & BeMiller (1973) and Glicksman (1969, 1982) provide four of the most useful treatises on applications of the different carrageenans and their modifications.

9.4 Animal Fodder

The carrageenans and Eucheuma are not normally used in animal fodder. However, the largest volume of alkali-treated Eucheuma is in pet foods where it is used as a powdered, granulated or hydrated gel component in the various formulations.

9.5 Manure

Eucheuma has essentially no use as a manure. Though its addition as an organic component in conditioning sandy soils is in some cases attractive, the cost is high. Some effort has been put forth to obtain use of the filter aid waste from the carrageenan extraction plants as a soil conditioner. Such waste filter aid is the major nonsoluble product from Eucheuma processing

9.6 Industrial products and processes

The carrageenans extracted from Eucheuma are modified by proprietary methods and even the relatively simple alkali-treatment process is hardly publicized. The assayed plant yields of extracted carrageenan may vary (Adnan & Porse In Mss) from 23 to 36 percent. A simple diagrammatic flow sheet is provided **(Figure 9)** though it is hardly applicable to any one actual alkali-modification plant.

The carrageenan extraction process itself is well known to be a hot water, high pH, process. The principal costs are in heat and separating the carrageenan from the extraction water. Three approaches are in use for water removal after centrifugation, filtering and sometimes vacuum removal of some water: a) spray drying on steam-heated drums as in the making of powdered milk, b) isopropanol extraction of the seaweed (when Chondrus is the source) such that the lambda carrageenan is separated from the kappa, with the kappa being extracted and precipitated separately later; and c) precipitation with alcohol. Each process has its merits, and some large companies use more than one method to obtain different qualities in their final products. Moss & Doty (In Press) provide a flow sheet **(Figure 10)** for the latter plant type.

Aside from the raw seaweed material, the principal costs of carrageenan (Moss & Doty, In Press) are in inventory, warehousing, water, power, alcohol recovery (only in alcohol precipitation plants), filter aid (diatomite or expanded mica as a rule) and chemicals (largely calcium and potassium hydroxides).

Figure 9. The alkali-treatment process for cottonii. Depending upon end product specifications, live or dried cottonii with or without preliminary treatment is often treated first in a hot alkali solution containing about 8.5 percent potassium hydroxide and then rinsed in successive tanks of water. The seaweed may be handled in baskets by an overhead traveling crane. Following a final draining, the treated material may be dried whole, or chopped and dried. The lower part of the figure shows a succession of processing steps that may follow depending on control laboratory analysis and desired nature of the final product

Figure 10. The alcohol process for carrageenan extraction with addition of ancillary space requirements. (From Moss & Doty In Press.)

ABSTRACT

Gelidium lingulatum A. Gardner and *G. rex* (Gigartinales) are the species currently harvested from central to southern Chile (33 to 41° S) at depths of 0 to 20 m. Their wild populations are found in the subtidal fringe and in the upper subtidal, on rocky substrata exposed to moderate to strong wave action. Their distribution is limited by the temperature regimen and by the atmospheric dryness in exposed areas. Vegetative reproduction is the only mechanism known for the maintenance of the populations. Sexual reproduction is rare and probably unimportant. Gametophytes are annual and tetrasporophytes are perennial. The latter have a life span of about 2.5 to 3 years. Tetrasporophytes are the only phase harvested. The harvest rate is about 1500 - 1800 tons (wet weight) per year. Harvesting is done by hand, by cutting the fronds with knives, leaving the holdfasts and basal portions of the stipes attached to the substratum. Regrowth takes place in about 6 months. Harvesting is done in a rotational basis, with a 2 year cycle. Management is based on the control of the harvesting season, the minimum size of the plants harvested, and the maximum harvesting rate. Cultivation methods have been developed for the species, but they are not yet commercially applied.

1. IDENTITY

1.1 Nomenclature
1.2 Taxonomy
1.3 Morphology and anatomy

1.1 Nomenclature

1.1.1 Valid scientific name

In Chile, three species of *Gelidium* are commercially important: *Gelidium pterocladia* (Montagne) Santelices et Montecinos, *G. lingulatum* Kutzing and *G. rex* Santelices et Montecinos.

1.1.2 Nomenclatural synonyms

The taxonomy of *Gelidium pterocladia* is thoroughly discussed by Santelices (1990 a, 1991). Previous to clarification the common species of *Gelidium* in Central Chile (Santelices & Montecinos 1990) was identified as *G. crinale* (Hare ex Turner) Lamouroux (Ramírez & Santelices 1982, Ramírez *et al.* 1986, Ramírez *et al.* 1987).

Gelidium lingulatum was described by A. Gardner (1927) from specimens collected from Talcahuano in central Chile (36° 43' S, 73° 7' W). It has been considered a synonym of *G. rex* by Santelices & Montecinos (1990) and by Santelices (1990 a, 1991). Type locality: Talcahuano, Chile.

Gelidium rex was described by Santelices & Montecinos (1990) from specimens collected at Quintay, Chile (33° 12' S, 71° 41' W). Type locality: Quintay, Chile.

1.2 Taxonomy

1.2.1 Affinities

1.2.2 Infraspecific taxonomy

The species of *Gelidium* belongs to the family Gelidiaceae, order Gigartinales, subclass Rhodymeniophycidae, class Florideophyceae, division Rhodophyta (Santelices 1990 a, Santelices & Montecinos 1990).

1.2.3 Genetic

The genus *Gelidium* was established by Lamouroux (1813) with the European species *Gelidium pulmoni* (Hudson) Lamouroux as the type. The following is a diagnosis of the genus:

The fronds are foliaceous, erect, prostrate or creeping, flattened, dichotomously branched, with a somewhat broad base and a thinner apical portion. The thallus is attached to the substratum by means of rhizoidal holdfasts, which are produced from the basal portion of the stipes. The thallus is differentiated into a cortex and a medulla. The cortex is composed of 2 to 4 layers of small, colorless cells, usually with conspicuous pit connections between adjacent cells. The medulla is composed of large, colorless cells with thick walls and pit connections between adjacent cells. Rhizoids are produced from the medullary cells. The medulla is also occupied by a conspicuous system of longitudinal, unbranched filaments of elongated cells, which are interpreted as gonimoblast filaments. Tetrasporangia are produced in sori in the cortex. Each tetrasporangium is surrounded by a group of sterile cortical cells. Tetrahedrally divided tetrasporangia are produced in the cortex. Spermatangia are produced in superficial, unspecialized areas on sporophyte and gametophyte thalli. Carpogonial branches are produced in the medullary region. Carpogonia are elongate, with a trichogyne. Cystocarps are urn-shaped, with a conspicuous ostiole. Carposporangia are produced in chains in the cystocarp cavity (Santelices & Montecinos 1990).

1.3 Morphology and anatomy

The plants of *Gelidium pterocladia* are foliaceous, erect, and dorsiventral. Axes are entire or a dorsal branch is laid with succinct and somewhat asteroid spines. Attachment is by means of rhizoidal holdfasts, which are produced from the basal portion of the stipes. Rhizoids are produced from the medullary cells. The thallus is differentiated into a cortex and a medulla, as in the genus. Cortical cells are isodiametric and similar to the rest. Medullary cells are elongated, thick-walled and generally producing secondary pits or fertile gonimoblast filaments. Tetrasporangia are produced in sori in the cortex. Each tetrasporangium is surrounded by a group of sterile cortical cells.

Anatomical of the frond (Fig. 1a) shows a cortex of 2 to 4 layers of small cells with conspicuous pit connections between the cells. The medulla is composed of colorless cells of up to 25× in diameter. Rhizoidal filaments are extensively abundant in lower cortex and outer parts of the medulla, decreasing in density towards the center.

Reproductive structures are found in the cortex. Tetrasporangia are produced in sori, which are superficial and scattered distributed in the basal half and irregularly expanded regions of each axes (Fig. 1b). They are produced each 10-20 in. in diam. and 50 in deep, in a cortex divided. Cystocarps are ovoid or conical. Gonidial branches are found in the medullary region. Carpogonia are elongate, with a trichogyne. Cystocarps are urn-shaped, with a conspicuous ostiole. Carposporangia are produced in chains in the cystocarp cavity.

Figure 1. Fertile fronds reproductive and anatomical structures in *Gelidium rex*. A. Tetrasporangial sorus, B. Cystocarp.

The plants of *Gelidium lingulatum* are erect, dorsiventral, with a somewhat broad base and a thinner apical portion. The thallus is attached to the substratum by means of rhizoidal holdfasts, which are produced from the basal portion of the stipes. The cortex is composed of 2 to 4 layers of small, colorless cells, usually with conspicuous pit connections between adjacent cells. The medulla is composed of large, colorless cells with thick walls and pit connections between adjacent cells. Rhizoids are produced from the medullary cells. The medulla is also occupied by a conspicuous system of longitudinal, unbranched filaments of elongated cells, which are interpreted as gonimoblast filaments. Tetrasporangia are produced in sori in the cortex. Each tetrasporangium is surrounded by a group of sterile cortical cells. Tetrahedrally divided tetrasporangia are produced in the cortex. Spermatangia are produced in superficial, unspecialized areas on sporophyte and gametophyte thalli. Carpogonial branches are produced in the medullary region. Carpogonia are elongate, with a trichogyne. Cystocarps are urn-shaped, with a conspicuous ostiole. Carposporangia are produced in chains in the cystocarp cavity (Santelices & Montecinos 1990).

2. DISTRIBUTION, ECOLOGY AND METHODS OBF

2.1 Geographic range
2.2 Habitat and ecological characteristics
2.3 Associated species
2.4 Distribution and growth

2.1 Geographic range

Gelidium lingulatum and *G. rex* have an approximately similar geographic distribution. *Gelidium rex* extends from 33° S to central Peru to approximately 30° S in central Chile (Santelices & Montecinos 1990). *Gelidium lingulatum* is found from 33° S to Chiloé Island (Santelices & Montecinos, 1990; Santelices and Abbott, 1987).

Gelidium lingulatum has been moderately collected from Talcahuano to Central Chile (ca 33° S) to Puerto Montt (41° S), Fonseca (1985) also reported the species from the Juan Fernández Islands (33° 37' S, 78° 50' W).

2.2 Local vertical and horizontal distribution

All three species of *Gelidium* occur as beds around the lower limits of the spring tides on rocky bottoms in exposed and semi-exposed habitats.

The maximum depth of *Gelidium rex* is 20 m in clear waters (Santelices and Abbott 1987) (Fig. 2a) and it occurs also in the lower portion of circalitoral or other types of rocky substrata (Santelices & Montecinos 1990). *Gelidium lingulatum* is found from the subtidal fringe to 10 m depth (Santelices & Montecinos 1990, Santelices and Abbott 1987).

Figure 2. Vertical distribution of *Gelidium rex* (Fig. 2a) and *G. lingulatum* (Fig. 2b) in wave exposed, rocky habitats of Central Chile.

Gelidium rex occurs in the exposed, wave-beaten habitats of the outer coast, where it is found as dense beds in the subtidal fringe and in the upper subtidal. *Gelidium lingulatum* is found in similar habitats, but it is also found in more protected habitats, such as the inner coast of bays and estuaries, where it is found as dense beds in the subtidal fringe and in the upper subtidal. Both species are found in habitats with exposed rock surfaces, with moderate to strong wave action, and with low to moderate sedimentation. Both species are found in habitats with low to moderate water movement, vertical walls, in locations in tidal rapids, and pools with low to moderate water movement (Santelices & Montecinos 1990).

Gelidium rex has the most restricted distribution. It occurs only on shallow subtidal reefs which are exposed to very strong waves and high water exchange rates.

2.3 Associated species

Associated species of *Gelidium* are listed in Table 1. Associated species of *Gelidium rex* are mostly subtidal species, such as *Durvillaea antarctica*, *Lessonia nigrescens*, *Macrocystis integrifolia*, *Iridaea laminarioides*, *Callophyllis variegata*, *Mazzaella laminarioides*, *Gigartina skottsbergii*, *Sarcothalia crispata*, *Chondracanthus chamissoi*, *Rhodymenia corallina*, *Corallina officinalis*, *Ulva rigida*, *Codium dimorphum*, *Codium fragile*, *Colpomenia peregrina*, *Scytosiphon lomentaria*, *Ectocarpus* sp., *Polysiphonia* sp., *Ceramium* sp., *Plocamium* sp., *Pterocladia* sp., *Gelidium lingulatum*, *Gelidium pterocladia*, *Gelidium chilense*, *Gelidium rex*, *Gelidium crinale*, *Gelidium* sp., *Gelidium* sp., *Gelidium* sp.,

The wild harvest and culture of Laminaria longicruris in Eastern Canada

ABSTRACT

Laminaria longicruris has formed an economic mainstay for the north, Inuit harvested it in 4000 Thule Times. Here this species has been put successively to human consumption and to industrial use. Its life history, ecology and productivity are described. Harvesting practices and their effects on the resource are discussed. Future prospects for the wild harvest are also considered.

1. IDENTITY

1.1 Nomenclature

1.1.1 Synonymies

1.1.2 Typification and Anatomy

1.1.1 Nomenclature

The species described as Laminaria longicruris de la Pylaie (1830), for Eastern Canada has become more synonymous reflected on the basis of misidentification. There are now 10 synonyms to show that. It was somehow the only species in the genus in Eastern Canada in the 1st 20th Century (Setchell and Gardner, 1919) for instance.

Recent taxonomic decisions (Chapman, 1974, Kain, 1979) indicate the following synonymy may be regarded as synonyms of L. longicruris: L. agardhii Kjell., L. farlowiana Jenn.

1.1.2 Synonymies

Laminaria longicruris belongs to the family Laminariaceae, order Laminariales, Division Phaeophyceae. The genus Laminaria is divided into sections Simplices and Digitatae (Kjellman, 1889). L. longicruris belongs to the section Simplices (Kain, 1979).

The North Atlantic species of the genus Laminaria are: L. digitata (Huds.) Lamx., L. hyperborea (Gunn.) Foslie, L. longicruris de la Pylaie, L. ochroleuca Bach. Pyl., L. solidungula J. Ag. and L. sinclairii (Harv. ex Hook. et Arn.) Farl., Anders. et Eat. (Chapman, 1974). The last two species are known only from the Pacific coast of North America. The distribution of L. digitata, L. hyperborea and L. ochroleuca in the NW Atlantic Laminaria-forming species may be south as far as Long Island (Mathieson et al., 1976). The species may occur further south on the European coast (Parke and Dixon, 1976). L. digitata is found in the Northern Hemisphere only, L. ochroleuca in the Southern Hemisphere and L. hyperborea in both. L. digitata and L. hyperborea are the two species in the section Digitatae (Kjellman, 1889). The species in the section Simplices are L. longicruris, L. sinclairii and L. solidungula.

There is a significant genetic component in the expression of shape and blade thickness in these Laminaria populations of Laminaria, section Simplices, (Chapman, 1975). Specimens of L. longicruris, L. sinclairii and L. solidungula have been grown in culture in the laboratory and in the field (Chapman, 1975). Specimens of L. longicruris have also been grown from spores and from the sporophytic tissue of the gametophyte (Chapman, 1973). See also Laminaria solidungula.

1.2 Morphology and Anatomy

The morphological characters that define the sporophytes of Laminaria longicruris are shown in Fig. 1. Size may attain with stipe up to 5 m and blades up to 2 m in length. Blade width may reach 0.5 m. Blade thickness may reach 1 mm. Blades are usually entire but may be split into a few segments. Blades are usually dark brown in colour.

Figure 1: Morphological form range in Laminaria longicruris (modified after Taylor, 1957, p.6) fig

The anatomy of Laminaria longicruris is typical for members of the genus as described by Parke (1948). The species has not been the subject of detailed fine structural investigation. The anatomy of L. digitata is typical for the genus and is described in the absence of knowledge of the anatomy of the species under discussion. The blade is composed of a meristoderm, a cortex and a medulla. The meristoderm is the photosynthetic tissue. The cortex is the storage tissue. The medulla is the conducting tissue. See the stipe do not. In more members laminaria in the stipe the cortex is the conducting tissue. The medulla is the storage tissue.

2. DISTRIBUTION, ECOLOGY AND METABOLISM

2.1 Geographical range

2.2 Environmental relations

2.3 Effects of ecological determinants

2.4 Local vertical and horizontal distributions

2.1 Geographical range

The species occurs widely throughout the NW Atlantic and eastern Arctic Oceans (Scott, 1894; Lee, 1980), mostly within Canadian territorial waters, and along the east coast of Greenland (Rosenvinge, 1898; Lee, 1980). In the NW Atlantic Laminaria longicruris occurs from Cape Cod, Massachusetts to Ungava Bay, Quebec (Mathieson et al., 1976). It is absent from the Bay of Fundy and the Gulf of St. Lawrence (Taylor, 1957). It is absent from the Arctic Ocean at Alaska (Lee, 1980).

In the NW Atlantic Laminaria longicruris forms the kelp zone of the Arctic Basin and of Boreal Atlantic Province (Mathieson et al., 1976). The species may occur further south on the European coast (Parke and Dixon, 1976). It is absent from the Arctic Ocean at Alaska (Lee, 1980). In the eastern Arctic Ocean, L. longicruris grows only to a depth of about 10 m (Scott, 1894). In the eastern North

The major effect of a summer depletion of available nitrogen in seawater is to simulate seasonal growth patterns from seasonal variations in light availability and temperature. Nitrogen depletion in the Gulf of Maine (Fig. 1) and in the Bay of Fundy (Chapman and Craigie, 1977) has been shown to produce seasonal growth patterns at sites in eastern Canada that do not experience a true winter season. Nitrogen reduction in the Gulf of Maine in late summer is the result of a thermal linear growth track seasonal variations in light availability when nitrogen supply is elevated during the summer months.

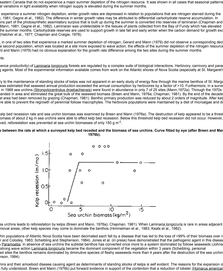

Fig. 1. Relationship between the ratio at which a surveyed kelp bed cleared and the biomass of sea urchins. Curve fitted by eye (after Breen and Mann, 1976).

Experimental removal of sea urchins leads to reforestation by kelps (Breen and Mann, 1976; Chapman, 1981). When *Laminaria longicruris* is rare in areas adjacent to experimental sea urchin removal areas, other kelp species may invade the cleared area (Chapman, 1978; Mann, 1977; Reed et al., 1980).

Beginning in 1980, sea urchin populations of Atlantic Nova Scotia have been decimated each fall by a disease that has led to the loss of >90% of their biomass over nearly 1,000 km of coastline (Miller and Colodey, 1983; Scheibling and Stephenson, 1984). Sea urchins of all size classes have been affected but the pathogen(s) appear to have a greater impact on the larger individuals. In absence of sea urchins the kelp bed ecosystem has converted since mid-to-s system dominated by foliose seaweeds (Johnson, 1984; Scheibling, 1986). Sea urchin populations have not recovered from the disease (Scheibling and Hennigar, 1988; Scheibling et al., 1988). Consequently, it is unclear if the kelp-to-urchin reversal documented by Breen and Mann (1976) and Chapman and Johnson (1990) can occur in the absence of sea urchins.

The importance of sea urchins and their annotated disease causing agent as determinants of standing stocks of kelps is self-evident. The reasons for the expansion of other populations after sea urchin removal and the factors that prevent or delay sea urchin recolonization (Mann, 1982; Breen and Mann, 1983) are less obvious. Sea urchin stocks left to an increase in sea urchin population densities. The evidence is follows: (a) lobsters appear likely as key predators of sea urchins, (b) lobsters have been overfished throughout the Atlantic coast of Canada (Scheibling and Robert, 1988; Scheibling et al., 1988), and (c) lobster landings have declined since 1980. It hypothesis that the lobster is a stabilizer predator of the kelp bed ecosystem (Steneck et al., 1983). Overfishing of lobsters has caused Laminaria densities to decline. It is difficult to separate the effects of overfishing from those of disease in the lobster population. Nevertheless, the lobster fishery is a major industry in Atlantic Canada. In this respect the predation hypothesis of Breen and Mann (1976b) remains untested, but it needs to be pointed out there is no evidence in support of its rejection.

It is more recent graphical model (Fig. 2) that has been developed to explain the alternative stable states of kelp bed ecosystems (Scheibling et al. in the Mann (1981) team incorporated the effects of fertilizer grazer, sea urchin) along with the effects of lobsters. The model also takes into account the behavioural responses of urchins to their predators. The key to kelp bed stability is the behaviour of sea urchins. Urchins will not graze on kelps if they are well fed (Mann, 1982) and these urchin densities are low. The presence of lobsters leads to the formation of aggregations which can maintain low urchin densities.

Figure 15. Graphical model of feedback relationship between kelp bed destruction and declining lobster stocks in the northwest Atlantic (after Wharton and Mann, 1981).

Johnson (1984) has studied the biological determinants that influenced the development of kelp stands following the disappearance of major sea urchin populations in St. Margaret's Bay, Nova Scotia. Kelp recruitment was found to be greatest in areas where adult kelp densities were low and where the substratum was covered by coralline algae. St. Margaret's Bay crustose coralline covered >80% of available substratum in areas where kelp recruitment was high. Experimental plots in Atlantic sea urchin removal areas (Fig. 3) also to demonstrate experimentally that the standing stock development of seaweeds growing on Phymatolithon was reduced by 40% in comparison with standing stock development of seaweeds growing on bare rock (Johnson and Mann, 1986; Scheibling, 1986).

The major growth of *Laminaria longicruris* in the absence of sea urchins is *Agarum cribrosum* (Mertens) Bory. Between February and September of 1982 the stipes consumed only 0.05% of the blade biomass available to them. The major effect of kneel grazing is to increase the ripping and loss of parts of the blade canopy. Johnson (1984) estimated that the standing biomass of *L. longicruris* in the Bay of Fundy was about 20% higher in the absence of sea urchins.

Chapman (1984) noted that in the kelp beds of the southwestern part of Nova Scotia, where sea urchins have never been recorded in high densities, interactions with fishes may be important in the control of kelp bed structure. Fishes are known to consume the sporophytes of *Laminaria saccharina* (Linnaeus) Lamouroux, *Alaria esculenta* (Linnaeus) Greville and *Agarum cribrosum* in the cold-temperate waters of Europe (Hemmingsen, 1960; Kennedy and Fitzpatrick, 1986). Fishes also consume the sporophytes of *Laminaria digitata* (Hudson) Lamouroux and *Laminaria hyperborea* (Gunnerus) Foslie

ABSTRACT

Laminaria is not a native of Chinese shores though it has been a well-known food commodity on the Chinese market for more than two thousand years. It was first imported in China from Korea and Japan. Laminaria japonica Aresch. was introduced to the Dalian area in 1927 and to Qingdao in 1928. Its cultivation began in 1952 and has since developed into a major industry. Laminaria japonica Aresch. is the only species cultivated on a large scale in China. Laminaria longissima Miyabe, L. ochotensis Miyabe, L. angustata Kjellm. and L. cichorioides (Miyabe) Miyabe et Miyake have been introduced and tested successfully. Of these the yield of L. longissima is comparable to that of L. japonica. Laminaria saccharina (L.) Lamour. is native to China but is of minor importance. Hybridization between L. japonica and L. longissima has been successful. Laminaria farlowii Setch. et Gard. is native to China and is grown on farms. Interspecific "fertile" x sterile and inter-varietal "fertile" x "fertile" crosses have been successful. Laminaria farlowii Setch. et Gard. is native to China and is grown on farms. Interspecific "fertile" x sterile and inter-varietal "fertile" x "fertile" crosses have been successful. Laminaria cichorioides (Miyabe) Miyabe et Miyake is native to China and is grown on farms. Interspecific "fertile" x sterile and inter-varietal "fertile" x "fertile" crosses have been successful. Laminaria angustata Kjellm. is native to China and is grown on farms. Interspecific "fertile" x sterile and inter-varietal "fertile" x "fertile" crosses have been successful. Laminaria ochotensis Miyabe is native to China and is grown on farms. Interspecific "fertile" x sterile and inter-varietal "fertile" x "fertile" crosses have been successful. Laminaria longissima Miyabe is native to China and is grown on farms. Interspecific "fertile" x sterile and inter-varietal "fertile" x "fertile" crosses have been successful. Laminaria saccharina (L.) Lamour. is native to China and is grown on farms. Interspecific "fertile" x sterile and inter-varietal "fertile" x "fertile" crosses have been successful. Laminaria japonica Aresch

ABSTRACT

This is one of a number of reports on Giant Kelp (*Macrocystis pyrifera*). This one gives a long list of topics which may be relevant to the commercial harvesting of the resource. Each topic is then discussed briefly. Many of the topics are discussed in greater detail in other reports in this series. Most of the discussion is based on the author's experience in California.

1. IDENTITY

1.1 Nomenclature
1.2 Taxonomy
1.3 Morphology and anatomy

1.1 Nomenclature

The genus *Macrocystis* Kützing (Agardh, 1820) (Tribe I, Laminariales, Family I, Laminariaceae, Subfamily I, Macrocystoideae, Genus I) is distinguished by its unique morphology. Its blades are borne on long, slender stipes which arise from a discoid holdfast. Each blade has a pneumatocyst at its base. The sporophyte is perennial. Its sporangia are borne in sori on sporophylls which are clustered near the base of the stipe. The gametophytes are microscopic, filamentous, dioecious, and isomorphic.

Three species of giant kelp are recognized by Setchell and Gardner (1925). They are distinguished by the number of blades per mature sporophyte and by the position of the sporophylls. *M. pyrifera* (Linnaeus) C. Agardh (1820) has many blades per sporophyte and sporophylls which are clustered near the base of the stipe. *M. integrifolia* Bory (1826) has few blades per sporophyte and sporophylls which are clustered near the base of the stipe. *M. angustifolia* Bory (1826) has many blades per sporophyte and sporophylls which are distributed along the stipe. Setchell and Gardner (1925) also described a number of varieties and forms. Most of these are based on the shape of the blades. Some are based on the position of the sporophylls. Some are based on the habit of the plant. Some are based on the habitat in which the plant grows.

Setchell and Gardner (1925) described a number of hybrids between species of *Macrocystis*. Hybrids between *M. pyrifera* and *M. integrifolia* have been found in the wild (Neushul, 1959). Hybrids between *M. pyrifera* and *M. angustifolia* have been found in the wild (Neushul, 1959). Hybrids between *M. integrifolia* and *M. angustifolia* have been found in the wild (Neushul, 1959). Hybrids between *M. pyrifera* and *M. integrifolia* have been found in the wild (Neushul, 1959). Hybrids between *M. pyrifera* and *M. angustifolia* have been found in the wild (Neushul, 1959). Hybrids between *M. integrifolia* and *M. angustifolia* have been found in the wild (Neushul, 1959).

1.2 Taxonomy

Macrocystis belongs to the order Laminariales, which includes those Phaeophyta growing by means of an intercalary meristem as well as a specialized transport system. Laminariales have chlorophyll *a* and chlorophyll *c*, fucoxanthin, and laminarin. Laminariales have the holdfast to differentiate into a blade and stipe, with the blade being split longitudinally. Laminariales have trumpet hyphae in the sieve elements of the phloem.

1.3 Morphology and anatomy

Microscopic stages in the *Macrocystis* life cycle (*i.e.*, gametophytes and immature sporophytes) resemble those of other members of the Laminariaceae (see below) and Lessoniaceae (see Neushul, 1972). Microscopic stages in the *Macrocystis* life cycle (*i.e.*, gametophytes and immature sporophytes) resemble those of other members of the Laminariaceae (see below) and Lessoniaceae (see Neushul, 1972). Microscopic stages in the *Macrocystis* life cycle (*i.e.*, gametophytes and immature sporophytes) resemble those of other members of the Laminariaceae (see below) and Lessoniaceae (see Neushul, 1972). Microscopic stages in the *Macrocystis* life cycle (*i.e.*, gametophytes and immature sporophytes) resemble those of other members of the Laminariaceae (see below) and Lessoniaceae (see Neushul, 1972).

Chromium	0.00125	0.0057	220

Bromine, Rubidium, and Fluorine are not concentrated.

9.2 Human Food

Usage of Macrocystis tissues as human food is minor in North America. Macrocystis and Nereocystis slices are occasionally prepared as pickles by individuals, but there is no known commercial product of this kind. Dried powdered kelp (probably *M. pyrifera*) was formerly marketed by Philip R. Park, Inc. A fraction of the product entered specialty items in health food stores (P. Neushul in Neushul and Harger, 1985).

9.3 Animal fodder and feed additives

Dried kelp (probably Macrocystis pyrifera) was formerly produced by Philip R. Park Inc. and Kelp Organic Products Co. of Los Angeles. Most of the material was incorporated into animal feeds. Neither of these concerns exist at this time (P. Neushul, 1.c.). The value of this Macrocystis as fodder might be enhanced by fertilizing shortly before harvesting to increase nitrogen and phosphorus contents of the tissues via (cf. Mateus et al., 1976) its amino acid composition.

9.4 Manure and fertilizer

No present usage of Macrocystis as a manure exists in California. A large and successful effort was mounted during the first World War to secure kelp as a source of potash for manufacture of fertilizer and explosives (Cameron, 1915; Scofield, 1959; P. Neushul, 1.c.). Presently, at Macrocystis harvested in California and Baja California is processed for alginate production and the resource is fully utilized. An economic study of the feasibility of using Macrocystis for methane production proposed dispersal of sludge remaining from digestion of the kelp, into their kelp farm as a fertilizer (Ralph M. Parsons, 1983).

9.5 Industrial products and processes

As noted above, alginates are the only products currently manufactured from harvested Macrocystis in California. Various compounds of the complex polysaccharides, alginic acid, serve as stabilizers, thickeners, emulsifiers, water-holders, and film-forming or suspending agents. Most of the usages are in foods, pharmaceuticals, beverages, dairy products, and in the manufacture of latex, textiles, as well as paper and cardboard, plus other miscellaneous uses (North, 1961; P. Neushul, 1.c.). Two methods for alginate manufacture are the Le Gloahec-Herter and Green's cold processes, both described with flow charts by Chapman (1970). Salts are first leached from cut or slurried kelp in weak acid. The alginate is then solubilized or induced to form a gel by soaking the kelp in a solution of sodium carbonate or other weak alkali. Reduction of pH by dilution with water or addition of acid causes precipitation and the recovered material can be sold as crude alginate or refined further by repeated solubilization and precipitation (Young, 1945).

In the past, a number of other industrial products have been derived from Macrocystis in California, particularly during the period of intense utilization during World War I. These included potash and acetone for explosives manufacturing (potash was also employed in manufacture of matches), iodine, and chart (P. Neushul, 1.c.). The early kelp industry was unable to compete with Chilean sources of potash which once more became available to American industry after the war in 1919. The California kelp industry collapsed for about a decade until interests in alginate production and the uses of kelp in animal feeds revived harvesting activities in 1927-28.

A possible future usage of Macrocystis is as alternative sources of energy in the form of gaseous or liquid fuels. The feasibility of liquid fuel production has already been demonstrated on a commercial scale by production of acetone in World War I by Hercules Powder Company (P. Neushul, 1.c.). Extensive investigations of the potential for methane production from kelp were recently completed (Tompkins and Bryce, 1984). This study, the Marine Biomass Program, also yielded considerable information relating to Macrocystis biology, and many of the resulting publications were cited above. We also referred to two of the economic analyses that were performed (Integrated Sciences, Inc., 1976; Ralph M. Parsons, 1983). Macrocystis tissue proved to be an excellent substrate for methane production by bacterial digestion processes. Yields of 4.5 SCF/16YVS (0.28 liters of combustible gas per gram of volatile solids) were reported by Chenoweth et al. (1978). Maximum methane yields were recovered from those kelp samples highest in mannitol.

In closing, we should mention that the Macrocystis forests in nature provide an extensive habitat for fishes and shellfish utilized by humans (North and Hubbs, 1968; Leighton, 1971). As such, Macrocystis and other large kelps are an important sustaining element in recreational and commercial fisheries, both of which are well-established activities in California.
